CROSS-REFERENCES TO RELATED APPLICATIONS

This application is a continuation application of U.S. patent application Ser. No. 13/463,735, filed May 3, 2012, which claims priority to U.S. Provisional Patent Application No. 61/483,036 filed May 5, 2011, commonly assigned and incorporated herein by reference for all purposes. This application is also related to U.S. patent application Ser. No. 12/756,861, filed Apr. 8, 2010, now U.S. Pat. No. 8,384,097, U.S. patent application Ser. No. 13/338,912, filed Dec. 28, 2011, and U.S. patent application Ser. No. 13/338,936, filed Dec. 28, 2011, now U.S. Pat. No. 8,399,268, all of which are commonly owned and incorporated herein by reference in their entirety.

BACKGROUND OF THE INVENTION

The present disclosure relates generally to lighting devises and methods for manufacturing and in particular to an LED-based high-power narrow beam light source for various applications.

As light-emitting diode (LED)-based lighting sources become popular, more customers are demanding high-power, narrow beam light sources. For example, in some high bay lighting applications, sufficient light may need to reach 12 meters or farther, and in some stage lighting applications, sufficient light may need to reach 40 to 60 meters. Conventional light apparatus for these applications often use large emitters and a reflector housing. The reflector is needed, because it would be difficult to use a very large secondary lens, e.g., a TIR secondary lens, with such large emitters. Conventional approaches have their limitations, as described in more detail below.

Therefore, it would be desirable to provide an improved LED-based light source.

BRIEF SUMMARY OF THE INVENTION

Embodiments of the present invention provide techniques related generally to lighting systems based on light-emitting diodes (LEDs). More particularly, embodiments of the present invention provide a total-internal-reflection (TIR) lens system that is preferably integrated with a small and high-power LED emitter. In some embodiments, the lighting systems can achieve ultra high lux at long distances using a single emitter. Merely by way of example, a spot TIR lens system integrated with an 80 W emitter is described for high bay lighting or stage lighting applications. But it will be recognized that the invention has a much broader range of applicability.

According to some embodiments of the present invention, a lamp includes a single emitter structure having a substrate with 25 or more light emitting diodes (LEDs) arranged thereon and a power rating of 80 Watts or more, a total internal reflection (TIR) lens, and a holder. The lens includes an optical body member having a substantially straight interior open channel in a lower portion thereof, the interior open channel having a lower opening for accommodating the single emitter structure. The optical body member has a step-shaped upper surface defining an increasingly wider cavity extending from an interior portion to an upper opening in of the optical body and a plurality of refractive surface regions disposed on the step-shaped upper surface of the

optical body. The holder has a concave interior surface shaped to accommodate the optical body member and a convex exterior surface. The holder also has a first opening disposed to surround the lower opening of the optical body member and a second opening opposite the first opening, wherein the optical body member is insertable into the holder through the second opening. The holder further also includes a plurality of tabs disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens, a finger-width sized cut-out, and three or more support members disposed surrounding the first opening of the holder and configured for centering the optical body member with respect to the single emitter structure.

In an embodiment of the above lamp, the lens includes a mixture of hardener over base resin, with a weight ratio of hardener over base resin less than 6. In a specific embodiment, the base resin is PMMA and a weight ratio of the hardener over base resin of about 4.1 to 2.1. In another embodiment, the base resin is epoxy and a weight ratio of the hardener over base resin of about 4.1 to 2.1. In yet another embodiment, the base resin is silicone and a weight ratio of the hardener over base resin of about 4.1 to 2.1.

In some embodiments of the above lamp, the lamp is configured to provide uniform color light at three meters or farther. In an embodiment, the lamp is configured to provide FWHM (full width half max) of 15 degrees, with 80% optical efficiency, wherein the optical efficiency is defined as the ratio of the light output through the secondary TIR lens to the light output of the emitter. In some embodiment, the lamp is characterized by a diameter of 80 mm and a height of 50 mm.

According to another embodiment of the above lamp, a method for forming the lamp includes forming the lens by molding a mixture of hardener over base resin, with a weight ratio of hardener over base resin less than 6. In an embodiment, the base resin is PMMA and a weight ratio of the hardener over base resin of about 4.1 to 2.1. In another embodiment, the base resin is epoxy or silicone and a weight ratio of the hardener over base resin of about 4.1 to 2.1.

According to some other embodiments of the invention, a lamp, includes a single emitter structure having a substrate with a plurality light emitting diodes (LEDs) arranged thereon, a total internal reflection (TIR) lens, and a holder. The lens includes an optical body member having a substantially straight interior open channel in a lower portion thereof, the interior open channel having a lower opening for accommodating the single emitter structure. The optical body member has an upper surface defining an increasingly wider cavity extending from an interior portion to an upper opening in of the optical body and a plurality of refractive surface regions disposed on the upper surface of the optical body. The holder having a concave interior surface shaped to accommodate the optical body member and a convex exterior surface, the holder having a first opening disposed to surround the lower opening of the optical body member and a second opening opposite the first opening, wherein the optical body member is insertable into the holder through the second opening. The holder also has a plurality of tabs disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens and three or more support members disposed surrounding the first opening of the holder and configured for centering the optical body member with respect to the single emitter structure.

In an embodiment of the above lamp, the upper surface of the optical body member includes a plurality of steps. In

3

another embodiment, the lamp also includes a plurality of refractive surface regions disposed on upper surface of the optical body.

In an embodiment of the above lamp, the lens comprises a mixture of hardener over base resin, with a weight ratio of hardener over base resin 4.1 to 2.1. In another embodiment, the lens includes a mixture of hardener over base resin, with a weight ratio of hardener over base resin between 1.5:1 to 2.5:1.

According to some other embodiments of the invention, a lamp includes a single emitter structure having a substrate with 25 or more light emitting diodes (LEDs) arranged thereon and a power rating of 80 Watts or more, a total internal reflection (TIR) lens with a plurality of refractive surface regions disposed on the step-shaped upper surface of the optical body, and a holder having a plurality of tabs disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens, and three or more support members configured for centering the optical body member with respect to the single emitter structure. In a specific embodiment, the lens includes a mixture of hardener over base resin, with a weight ratio of hardener over base resin less than 6. In another embodiment, the lens includes a mixture of hardener over base resin, with a weight ratio of hardener over base resin between 1.5:1 to 2.5:1.

According to yet another embodiment of the invention, a method for forming a lens includes forming the lens by molding a mixture of hardener over base resin with a weight ratio of hardener over base resin less than 6. In a specific embodiment, the weight ratio of hardener over base resin between 1.5:1 to 2.5:1. In another embodiment, the weight ratio of hardener over base resin of 4.1:2.1.

The following detailed description together with the accompanying drawings will provide a better understanding of the nature and advantages of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a simplified cross-sectional side view of an LED-based lamp according to an embodiment of the present invention.

FIG. 2 is a simplified top view of a 25-die emitter implementing emitter package 104 of FIG. 1 according to a specific embodiment of the present invention.

FIG. 3 illustrates a perspective view of an exemplary lamp with an emitter, a holder, and a lens, separately and as an assembled lamp, respectively, according to an embodiment of the invention.

FIG. 4 shows a top view, a side view, and a cross-sectional view of the lamp of FIG. 3, respectively.

FIG. 5 shows a top view, side view, and a cross-sectional view of a lens according to an embodiment of the invention.

FIG. 6 shows another perspective view and top view of the lens of FIG. 5.

FIG. 7 illustrates various views of a lens holder according to an embodiment of the invention.

FIG. 8 illustrates top views of the lens holder of FIG. 7 according to an embodiment of the invention.

FIG. 9 illustrates a perspective view of a lens with a holder and a detailed view of an upper portion of the holder according, to an embodiment of the invention.

FIG. 10 illustrates perspective views of the lens and holder combination in separate and assembled positions, respectively, according to an embodiment of the invention.

4

FIG. 11 illustrates a top view and a cross-section view of the lens and holder combination in an assembly according to an embodiment of the invention.

DETAILED DESCRIPTION OF THE INVENTION

Embodiments of the present invention provide techniques related generally to lighting systems based on light-emitting diodes (LEDs). More particularly, embodiments of the present invention provide a total-internal-reflection (TIR) lens system that is preferably integrated with a small and high-power LED emitter. In some embodiments, the lighting systems can achieve ultra high lux at long distances using a single emitter. Merely by way of example, a spot TIR lens system integrated with an 80 W emitter is described for high bay lighting or stage lighting applications. But it will be recognized that the invention has a much broader range of applicability.

For example, in some high bay lighting applications, sufficient light may need to reach 12 meters, and in some stage lighting applications, sufficient light may need to reach 40 to 60 meters. Conventional light apparatus for these applications often use large emitters and a reflector housing. The reflector is needed, because it would be difficult to use a very large secondary lens, e.g., a TIR secondary lens, with such large emitters. Embodiments of the present invention, however, provide a TIR lens integrated with a single small and high-power LED emitter. Embodiments of the invention incorporate properties such as the light collimating capability of the TIR secondary lens and the high-power small emitter to enable the high lux at long distances.

In some embodiments, the lighting system includes a 25-die emitter, which can have a size as small as 12 mm by 12 mm and can have a power rating of 80 W. The emitter includes 25

LED dice disposed on a multi-layered substrate. The small multi-layered substrate uses materials having matching thermal and mechanical properties that enable it to maintain its flatness without distortion when the attached emitter has power consumption as high as 80 W. A similar multi-layered substrate is described in commonly-owned U.S. patent application Ser. No. 12/756,861, whose entire content is incorporated by reference herein.

In some embodiments, the lighting system can have FWHM (full width half max) of 15 degrees, with 80% optical efficiency, and excellent intensity and color uniformity at 3 meters and above. Here, the 80% optical efficiency is defined as the ratio of the light output through the secondary TIR lens to the light output of the emitter.

In a specific embodiment, the multi-layered substrate with controlled CTE (coefficient of thermal expansion) allows emitters to use a glass primary lens without cracking. To the best knowledge of the inventors of this invention, it is difficult in a conventional lighting apparatus to use a glass lens on a high-powered LED or emitter, because thermal expansion mismatch can cause delamination or cracking.

More details of the lighting apparatus and various components are described below.

Optical Design:

Due to the size of the 80 W emitter, it is a challenging task to design an optics for this light source with specifications requiring high optical efficiency and excellent intensity and color uniformity at a narrow angle beam. FIG. 6 shows a perspective view and a top view of a TIR lens according to an embodiment of the invention. This innovative optical design combines a lens that features TIR property that

5

ensures high efficiency, micro-lens on top to provide good uniformity, large size to achieve narrow beam angle, and step structures to reduce lens mass. When a lens is large, the optical path is long. Therefore, the transmission loss becomes evident. In order to minimize the loss, the center portion of the lens is cut into steps, which does not alter the optical performance in terms of beam angle and beam uniformity. However, it reduces the mass of the lens, and reduces the transmission loss. It also makes manufacturing process shorter and easier. The combination of all the above features makes this lens unique for applications such as high bay lighting and stage lighting, which requires ultra high central lux with and superb color and intensity uniformity at long distance.

The following table summarized the optical performance of a specific TIR lens system according to an embodiment of the present invention.

	Lumens of 80 W emitter	
	700 mA	1000 mA
Optical efficiency (%)	81	81
On axis optical efficiency (Cd/lm)	8	8
View angle (FWHM, deg)	15	15
Dimensions (mm)	Diameter: 80 Height: 50	

In contrast, conventional optics lens system tends to be much larger and cannot provide the narrow view angle of 15 degrees described above. Some examples of conventional systems are listed in the table below.

	Dimensions	View angle
Conventional System #1	Diameter: 450 Height: 478	170
Conventional System #2	Diameter: 500 Height: 580	NA

It can be seen that the TIR lens system in embodiments of the invention is much smaller than conventional optics, e.g. 80x50 mm versus about 500x500 mm. An implication of the large size of conventional system is that it usually requires reflectors in the lens system. In contrast, in embodiments of the present invention, a secondary TIR lens can be used. The narrow view angle benefits from the small emitter and TIR lens. On the other hand, even though the 80x50 mm TIR lens enables the small lighting system, a single piece TIR lens of the size of 80x50 mm is considered relatively large in lens manufacturing and has not been available in the market, to the best knowledge of the inventors of this invention. As a result, a manufacturing method for such a large lens is quite different from conventional methods, as described below.

Manufacturing Method of the TIR Lens:

In some embodiments, methyl methacrylate “synthetic resin” for casting (simply the bulk liquid chemical) may be used in conjunction with a polymerization catalyst such as MEKP, to produce hardened transparent PMMA in any shape, from a mold. During the mold process, polymerization catalyst (the hardener) is added to the base resin for curing purpose. After mixing two materials, the chemical reaction will generate heat and the amount of heat is dependent on volume of the lenses and ambient temperature.

6

The heat can accumulate enough to cause browning of the lens, which can result in significant transmission loss.

The inventors of this invention have discovered that in order to successfully mold a lens with relative large sizes, it is important to understand the thermal property of the material and to optimize the manufacturing process. Otherwise, the overheating of the material will cause the browning of the lens, which will diminish lens efficiency. If the thermal stress of the material is not uniform across the lens, it will reduce material transmission efficiency; therefore, it also reduces optical efficiency significantly.

The inventors of this invention have discovered that to mold a large lens, the ratio of hardener/base resin needs to be optimized. For example, a lower ratio is needed for a large (volume) lens, and a lower ratio is needed when the ambient temperature is high.

In some embodiments, a lower ratio of hardener/base resin is used, and the resulting lens exhibits a lower transmission loss. Typically base resin and hardener ratios used in conventional methods are not suitable for making large lenses. Some examples of conventional methods are shown in the table below.

	PMMA	Epoxy	Silicone
Weight mixing ratio: Base resin to hardener	2:1 to 4:1	2:1 to 4:1	2:1 to 4:1

In contrast, the manufacturing of the large TIR lens described here uses a ratio range from 6:1 to 10:1.

In addition to the secondary TIR lens described here, other apparatus, such as Par 38 lenses and Par 30 lenses, can also benefit by the material optimization process because of their sizes.

Mechanical Retention Features:

In embodiments of the present invention, the lens holder is designed to meet at least the following two requirements: 1) firmly hold the lens, and 2) allow lens to be inserted and extracted from lens holder by hand or with light push/pull force. The lens is held firmly in lens holder by light radial compression fit between the flange diameter of the lens and the tabs on the inside rim of the lens holder. In a specific embodiment, on the inside rim of the lens holder, there are 14 tabs uniformly placed around the perimeter of the rim. The size and spacing of the tabs were designed and optimized to achieve this light press fit. On the perimeter of the lens holder’s rim, there is a finger width sized cut-out that does two things: 1) facilitate the flexing of the lens holder when extracting lens from the Holder, and 2) allows finger nail (or the edge of a small flat screw driver) to be inserted and used to pry out the lens from lens holder. Some of the features describe above are illustrated in FIGS. 7-9.

Conventional lens holders often have clips for holding the lens in the holder, and the clips often protrude from the rim. The clips are often broken when the lens is taken out of the holder, preventing the holder from being re-used. In embodiments of the invention, the lens holder has no protruding clips and can be re-used after the lens is taken out of the lens holder.

Examples of specific embodiments according to embodiments of the invention are described below.

FIG. 1 is a simplified cross-sectional side view of an LED-based lamp 100 according to an embodiment of the present invention. Lamp 100, which is cylindrically symmetric about an axis 101, has a housing 102, which can be made of aluminum, other metals, plastic, and/or other suit-

able material. Housing **102** holds the various components of lamp **100** together and can provide a convenient structure for a user to grip lamp **100** during installation or removal from a light fixture. The exterior of housing **102** can include mechanical and/or electrical fittings **103** to secure lamp **100** into a light fixture and/or to provide electrical power for producing light. In some embodiments, housing **102** may include fins or other structures to facilitate dissipation of heat generated during operation of lamp **100**. The exterior shape of housing **102** can be made to conform to a standard lamp form factors.

Within housing **102** is an emitter package **104**. Package **104** includes a substrate **106** in which is formed with a recess **107**. Substrate **106** can be a multilayer structure with ceramic and metal layers. Examples are described in U.S. Patent Application Pub. No. 2010/0259930, the disclosure of which is incorporated herein by reference. Other substrates can also be used.

LEDs **108** are mounted on substrate **106** within recess **107**. In some embodiments, the top surface of recess **107** is patterned with a number of metal pads, each accommodating a single LED **108**. Each LED **108** can be a separate semiconductor die structure fabricated to produce light of a particular color in response to electrical current. In some embodiments, LEDs **108** can be covered with a material containing a color-shifting phosphor so that LED **108** produces light of a desired color. For example, a blue-emitting LED die can be covered with a material containing a yellow phosphor; the emerging mixture of blue and yellow light is perceived as white light having a particular color temperature. As described below, in some embodiments different ones of LEDs **108** can produce light of different colors; LEDs **108** need not be identical.

Lamp **100** also includes a primary lens **110**, which can be made of glass, plastic, or other optically transparent material, that is positioned to direct light emitted from LEDs **108** into secondary optics **112**. Secondary optics **112** advantageously include a total-internal-reflection (TIR) lens that also provides mixing of the colors of light emitted from LEDs **108** such that the light beam exiting through front face **114** has a uniform color. Examples of suitable lenses are described in U.S. Patent Application Pub. No. 2010/0091491, the disclosure of which is incorporated herein by reference; other color-mixing lens designs may also be used.

In some embodiment, optionally lamp **100** can also include a diffusive coating **120** on front face **114** of lens **112**. Coating **120** provides further color mixing of the light exiting secondary optics **112** without requiring additional space, a significant consideration when designing a lamp with a compact form factor. Various coatings **120** can be used. In some embodiments, coating **120** can be a holographic diffuser film, such as a light-shaping diffuser film made by Luminit Co. of Torrance, Calif. (website at www.lumintco.com). In these films, the diffusive coating is provided as a diffusive material disposed in a desired pattern on an optically transparent substrate film (e.g., acrylic, polyester, polycarbonate, glass or fused silica). The film is easily applied to front face **114**. Other types of coatings can also be applied; for example, diffusive material can be applied directly to front face **114**.

In some embodiments, lamp **100** includes a control circuit **116** that controls the power provided from an external power source (not shown) to LEDs **108**. In some embodiments, control circuit **116** allows different amounts of power to be supplied to different LEDs **108**, allowing for tuning of the color as described below.

FIG. **2** is a simplified top view of a 25-die emitter **200** implementing emitter package **104** of FIG. **1** according to a specific embodiment of the present invention. In this embodiment, substrate **206** includes a recess **207** in which 25 LEDs **208** are disposed in a 5×5 grid as shown.

In some embodiments, emitter **200** can include LED dice of different colors. For example, each white LED die can include a blue light LED chip with a wavelength-converting layer disposed directly thereon, and each red LED die includes a red light LED chip. In some embodiments, the white LED dice are selected to produce a cool white, warm white, or an off-white color, e.g., a greenish white color, with a desired amount of wavelength-converting material is disposed directly on the blue light LED chip. When light from the different color dice is mixed by mixing lens **112**, a desired light color temperature can be achieved.

As used herein, “cool” white and “warm” white refer to the color temperature of the light produced. Cool white, for example, can correspond to a color temperature above, e.g., about 4000 K, while warm white can correspond to a color temperature below, e.g., about 3000 K. Further, the terms “white light” or “white color”, as used herein, can refer to a broad range of whitish colors or light, for example, cool white, warm white, greenish white, and reddish white, etc.

In some embodiments, LEDs **208** are advantageously provided with electrical connections such that different groups of the LEDs are independently addressable, i.e., different currents can be supplied to different groups of LEDs. These electrical connections can be implemented, e.g., using traces disposed on the surface of substrate **206** and/or between electrically insulating layers of substrate **206**.

Where the different LED groups are interpedently addressable, package **200** provides an emitter that can be tuned to produce light of a desired color (e.g., color temperature) by adjusting the relative current delivered to different groups of LEDs **208**, e.g., using control circuit **116**. Techniques for tuning an emitter have been described, e.g., in U.S. patent application Ser. No. 13/106,808 and U.S. patent application Ser. No. 13/106,810, the disclosures of which are incorporated herein by reference.

In other embodiments, the color temperature of the light produced by the lamp can be controlled by selecting the LEDs such that the desired color (e.g., color temperature) is achieved when equal currents are supplied to all LEDs **208**. In other embodiments, the color temperature of the light produced by the lamp can be controlled by selecting white LED dice (W) and red LED dice (R) such that the desired color (e.g., color temperature) is achieved when equal currents are supplied to all LEDs. Selection of LEDs for a given substrate can be done by testing individual LED dice prior to substrate assembly to determine the color temperature of light produced and binning the LED dice according to color temperature. Accordingly, color tuning by adjusting the relative current supplied to different groups of LEDs is not required.

In the embodiment of FIG. **2**, the LEDs are arranged to provide a roughly uniform circular distribution of the LEDs. That is, the white and red LEDs are intermixed and arranged such that warm and cool light are produced in approximately equal intensities across different parts of the emitter substrate. This allows for optimal color mixing using secondary optics such as TIR lens **112** of FIG. **1**, to produce a uniformly white light from LEDs that are not uniform in color.

With reference to the description of lamp **100** above, various specific embodiments are described below.

According to some embodiments of the present invention, a lamp includes a single emitter structure having a substrate with a plurality of light emitting diodes (LEDs) arranged thereon and, a total internal reflection (TIR) lens, and a holder. FIG. 3 illustrates a perspective view of an exemplary lamp 300 with an emitter 310, a holder 320, and a lens 330 separately and as an assembled lamp, respectively. In some embodiment, the emitter can have 25 or more light emitting diodes (LEDs) and a power rating of 80 Watts or more. FIG. 4 shows a top view, a side view, and a cross-sectional view of lamp 300, respectively.

FIG. 5 shows a top view, side view, and a cross-sectional view of a lens 500 according to an embodiment of the invention. As shown, lens 500 includes an optical body member 510 having a substantially straight interior open channel 512 in a lower portion thereof. The interior open channel 512 has a lower opening 513 for accommodating the single emitter structure. The optical body member has a step-shaped upper surface 515 defining an increasingly wider cavity 516 extending from an interior portion to an upper opening in of the optical body and a plurality of refractive surface regions 518 disposed on the step-shaped upper surface of the optical body. FIG. 6 shows another perspective view and top view of lens 500.

FIG. 7 illustrates various views of a lens holder according to an embodiment of the invention. As shown, holder 700 has a concave interior surface 710 shaped to accommodate the optical body member of the lens and a convex exterior surface 720. The holder also has a first opening 712 disposed to surround the lower opening of the optical body member and a second opening 714 opposite the first opening, wherein the optical body member is insertable into the holder through the second opening. Holder 700 also has three or more support members 716 disposed surrounding the first opening of the holder and configured for centering the optical body member with respect to the single emitter structure. As illustrated in FIG. 8, the holder further also includes a plurality of tabs 810 disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens. The holder also has a finger-width sized cut-out 820 for handling the insertion and removal of the lens into and out of the holder.

FIG. 9 illustrates a perspective view of a lens with a holder and a detailed view of an upper portion of the holder. Specifically the flange of the lens, and the tabs and rim of the holder are shown. FIG. 10 illustrates perspective views of the lens and holder combination in separate and assembled positions, respectively, according to an embodiment of the invention. FIG. 11 illustrates a top view and a cross-section view of the lens and holder combination in an assembly according to an embodiment of the invention.

In an embodiment of the above lamp, the lens includes a mixture of hardener over base resin, with a weight ratio of hardener over base resin less than 6. In a specific embodiment, the base resin is PMMA and a weight ratio of the hardener over base resin of about 4.1 to 2.1. In another embodiment, the base resin is epoxy and a weight ratio of the hardener over base resin of about 4.1 to 2.1. In yet another embodiment, the base resin is silicone and a weight ratio of the hardener over base resin of about 4.1 to 2.1.

In some embodiments of the above lamp, the lamp is configured to provide uniform color light at three meters or farther. In an embodiment, the lamp is configured to provide FWHW (full width half max) of 15 degrees, with 80% optical efficiency, wherein the optical efficiency is defined as the ratio of the light output through the secondary TIR lens

to the light output of the emitter. In some embodiment, the lamp is characterized by a diameter of 80 mm and a height of 50 mm.

According to some other embodiments of the invention, a lamp includes a single emitter structure having a substrate with 25 or more light emitting diodes (LEDs) arranged thereon and a power rating of 80 Watts or more, a total internal reflection (TIR) lens with a plurality of refractive surface regions disposed on the step-shaped upper surface of the optical body, and a holder having a plurality of tabs disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens, and three or more support members configured for centering the optical body member with respect to the single emitter structure. In a specific embodiment, the lens includes a mixture of hardener over base resin, with a weight ratio of hardener over base resin less than 6. In another embodiment, the lens includes a mixture of hardener over base resin, with a weight ratio of hardener over base resin between 1.5:1 to 2.5:1. Some of the above features are illustrated in the figures described above.

According to yet another embodiment of the invention, a method for forming a lens includes forming the lens by molding a mixture of hardener over base resin with a weight ratio of hardener over base resin less than 6. In a specific embodiment, the weight ratio of hardener over base resin between 1.5:1 to 2.5:1. In another embodiment, the weight ratio of hardener over base resin of 4.1:2.1.

According to another embodiment of the above lamp, a method for forming the lamp includes forming the lens by molding a mixture of hardener over base resin, with a weight ratio of hardener over base resin less than 6. In an embodiment, the base resin is PMMA and a weight ratio of the hardener over base resin of about 4.1 to 2.1. In another embodiment, the base resin is epoxy or silicone and a weight ratio of the hardener over base resin of about 4.1 to 2.1.

Thus, although the invention has been described with respect to specific embodiments, it will be appreciated that these examples are not limiting, and that the invention is intended to cover all modifications and equivalents within the scope of the disclosure.

What is claimed is:

1. A lamp, comprising:

a single emitter structure having a substrate with a plurality light-emitting diodes (LEDs) arranged thereon; a total-internal-reflection (TIR) lens, the TIR lens including:

an optical body member having a substantially straight interior open channel in a lower portion thereof, the interior open channel having a lower opening for accommodating the single emitter structure;

the optical body member having a step-shaped upper surface defining an increasingly wider cavity extending from an interior portion to an upper opening of the optical body; and

a plurality of refractive surface regions disposed on the step-shaped upper surface of the optical body.

2. The lamp of claim 1, wherein the single emitter structure comprises 25 or more light-emitting diodes (LEDs) arranged on the substrate and a power rating of 80 Watts or more.

3. The lamp of claim 1, further comprising a holder having:

a concave interior surface shaped to accommodate the optical body member;

a convex exterior surface;

11

- a first opening disposed to surround the lower opening of the optical body member and a second opening opposite the first opening, wherein the optical body member is insertable into the holder through the second opening;
- a plurality of tabs disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens; and
- three or more support members disposed surrounding the first opening of the holder and configured for centering the optical body member with respect to the single emitter structure.
4. The lamp of claim 1, wherein the lamp is configured to provide uniform color light at three meters or farther.
5. The lamp of claim 1, wherein the lamp is configured to provide FWHW (full width half max) of 15 degrees, with 80% optical efficiency, wherein the optical efficiency is defined as the ratio of the light output through the secondary TIR lens to the light output of the emitter.
6. The lamp of claim 1, wherein the lamp is characterized by a diameter of 80 mm and a height of 50 mm.
7. A lamp, comprising:
- a single emitter structure having a substrate with a plurality light-emitting diodes (LEDs) arranged thereon; and
- a total-internal-reflection (TIR) lens, the lens including:
- an optical body member having a substantially straight interior open channel in a lower portion thereof, the interior open channel having a lower opening for accommodating the single emitter structure;
- the optical body member having an upper surface defining an increasingly wider cavity extending from an interior portion to an upper opening of the optical body; and
- a plurality of refractive surface regions disposed on the upper surface of the optical body.
8. The lamp of claim 7, wherein the upper surface of the optical body member comprises a plurality of steps.
9. The lighting apparatus of claim 8, further comprising a plurality of refractive surface regions disposed on upper surface of the optical body.
10. The lamp of claim 7, wherein further comprising a holder having:
- a concave interior surface shaped to accommodate the optical body member;
- a convex exterior surface;
- a first opening disposed to surround the lower opening of the optical body member and a second opening opposite the first opening, wherein the optical body member is insertable into the holder through the second opening;
- a plurality of tabs disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens; and
- three or more support members disposed surrounding the first opening of the holder and configured for centering the optical body member with respect to the single emitter structure.
11. A lamp, comprising:
- a single emitter structure having a substrate with a plurality light-emitting diodes (LEDs) arranged thereon;
- a total-internal-reflection (TIR) lens, the lens including a plurality of refractive surface regions disposed on a step-shaped upper surface of the optical body; and
- a holder having a plurality of tabs disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens, and three or

12

- more support members configured for centering the optical body member with respect to the single emitter structure.
12. The lamp of claim 11, wherein in the single emitter structure comprises with 25 or more light-emitting diodes (LEDs) arranged on the substrate and a power rating of 80 Watts or more.
13. The lamp of claim 12, wherein the lamp is configured to provide FWHW (full width half max) of 15 degrees, with 80% optical efficiency, wherein the optical efficiency is defined as the ratio of the light output through the secondary TIR lens to the light output of the emitter.
14. The lamp of claim 12, wherein the lamp is characterized by a diameter of 80 mm and a height of 50 mm.
15. A lens assembly, comprising:
- a total-internal-reflection (TIR) lens, the lens including:
- an optical body member having a substantially straight interior open channel in a lower portion thereof, the interior open channel having a lower opening for accommodating a light source;
- the optical body member having a step-shaped upper surface defining an increasingly wider cavity extending from an interior portion to an upper opening of the optical body; and
- a plurality of refractive surface regions disposed on the step-shaped upper surface of the optical body.
16. The lens assembly of claim 15, further comprising a holder having:
- a concave interior surface shaped to accommodate the optical body member;
- a convex exterior surface;
- a first opening disposed to surround the lower opening of the optical body member and a second opening opposite the first opening, wherein the optical body member is insertable into the holder through the second opening;
- a plurality of tabs disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens; and
- three or more support members disposed surrounding the first opening of the holder and configured for centering the optical body member with respect to the single emitter structure.
17. A lens assembly, comprising:
- a total-internal-reflection (TIR) lens, the lens including:
- an optical body member having a step-shaped upper surface defining an increasingly wider cavity extending from an interior portion to an upper opening of the optical body.
18. The lens assembly of claim 17, wherein the optical body member further comprises a plurality of refractive surface regions disposed on the step-shaped upper surface of the optical body.
19. The lens assembly of claim 18, wherein the optical body member further comprises a substantially straight interior open channel in a lower portion thereof, the interior open channel having a lower opening for accommodating a light source.
20. The lens assembly of claim 19, further comprising a holder having:
- a concave interior surface shaped to accommodate the optical body member;
- a convex exterior surface;
- a first opening disposed to surround the lower opening of the optical body member and a second opening oppo-

site the first opening, wherein the optical body member is insertable into the holder through the second opening;

a plurality of tabs disposed along an inside rim of the holder and configured for radial compression fit with a flange of the lens; and

three or more support members disposed surrounding the first opening of the holder and configured for centering the optical body member with respect to the single emitter structure.
